

Logistic Regression

Who is Willing to Commute Long Distances?

Zi Ye
ENVS225
Exploring the Social World

So far - Multiple Linear Regression

$$Y = \beta_0 + \beta_1 X 1 + \beta_2 X 2 + \beta_3 X 3 + \epsilon$$

$$Scale/Continuous variables$$

$$Dummy variables$$

Scale/Continuous variables

But - Categorical Dependent Variables

$$Y = \beta_0 + \beta_1 X 1 + \beta_2 X 2 + \beta_3 X 3 + \epsilon$$

Categorical variables

Binominal logistic regression for binary variable: 0 or 1

- Examples:
 - Health outcomes/behaviours
 - · eg. smoking, drinking, cancer, heart attack, HIV, etc.
 - Employment outcomes
 - unemployed, employed full-time, employed part-time, self-employed, job satisfaction, etc.
 - Decision making processes
 - · Brexit vote, travelling, migration, long-distance commuting, etc.

Learning Outcomes

Aim: Understanding how to estimate and interpret a <u>logistic regression model</u>

Binominal logistic regression for binary variable: 0 or 1

Estimate and interpret a logistic regression model

Make predictions using a logistic regression

Assess the model fit

What is a Logistic Regression?

Logistic regression

- Used to calculate the probability of a binary event occurring.
- and to deal with issues of classification.

- Pass the examination (1: Yes; 0: No)
- Disease (1: Yes; 0: No)
- Online purchase (1: Will buy; 0: No)
- Vote for candidate: (1: Will vote; 0: No)
- etc.

From Probability to Odds

Everything starts with the concept of probability.

Let's say that the probability of success of some event is p = 0.8

Then the probability of failure is 1 - p = 0.2

The odds of success are defined as the ratio of the probability of success over the probability of failure.

Odds of success are
$$\frac{p}{1-p} = 0.8/0.2 = 4$$

We say the odds of success are 4 to 1.

If the probability of success is 0.5, i.e., 50-50 % chance, then the odds of success is 1 to 1.

From probability to odds to log of odds

$$\frac{p}{1-p}$$
 Odds: from 0 to $+\infty$

$$log\left(\frac{p}{1-p}\right)$$
 Log Odds: from - ∞ to + ∞

Logistic Regression

Y — takes values of 1 or 0

p is the probability of the event occurring: Y=1

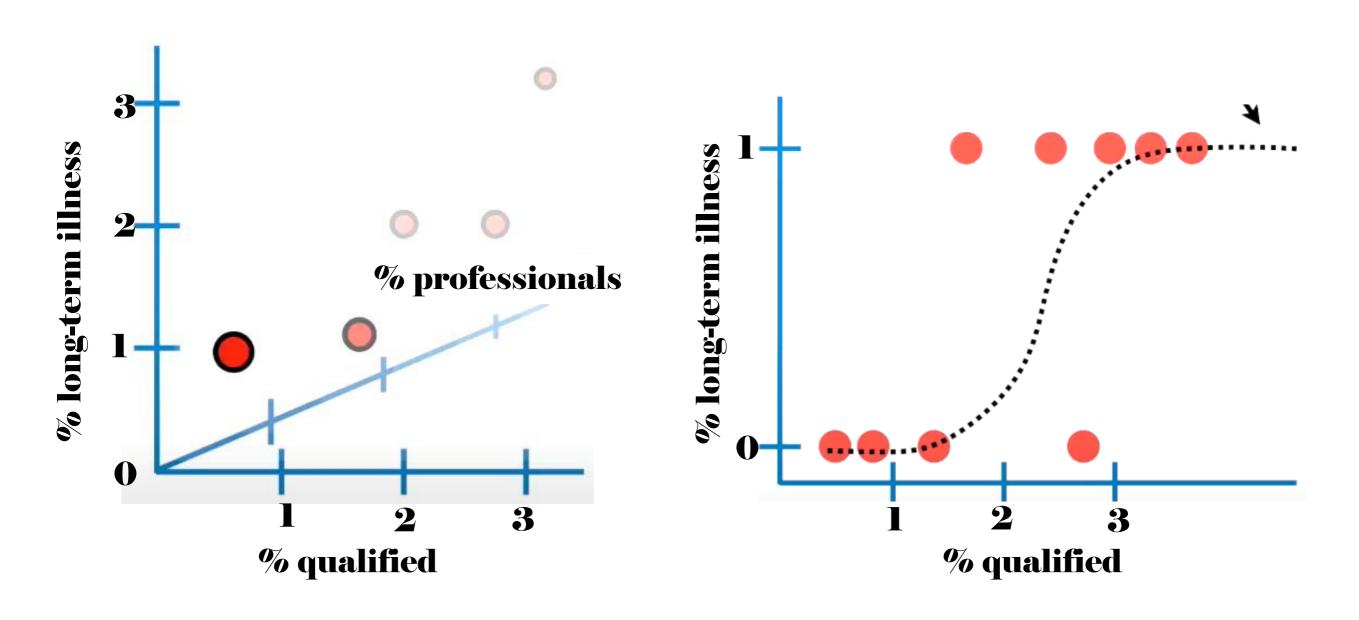

Log odds

$$logit(p) = log\left(\frac{p}{1-p}\right) = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \varepsilon$$

THE LOGISTIC EQUATION

Linear vs logistic

What Does a Logistic Regression Do?

- Predict the probability of an event happening based on at least one independent variable
 - vs. linear regression estimates the average value
- Dependent variable: qualitative (dummy or binary) variable
 - vs. linear regression continuous variable
- Requires estimates of the dependent variable to lie between 0 and 1 (i.e. positive values)
 - vs. linear regression continuous variable

Also Known as

- binary regression model
- Logit model
- discrete choice model
- probability regression model
- qualitative response regression model

Interpretation of β s

Intercept

• Is the <u>log-odds</u> of an event happening (i.e. Y=1) if the value of the explanatory variables Xs is zero.

Slope

• Is the <u>estimated change in the log-odds</u> for one unit change in X_k, holding all other variables constant.

Interpretation of Exp(\betas) Odds Ratio

Calculates the relationship between a variable (e.g., % qualifications) and the likelihood of an event occurring (e.g., % long-term ill)

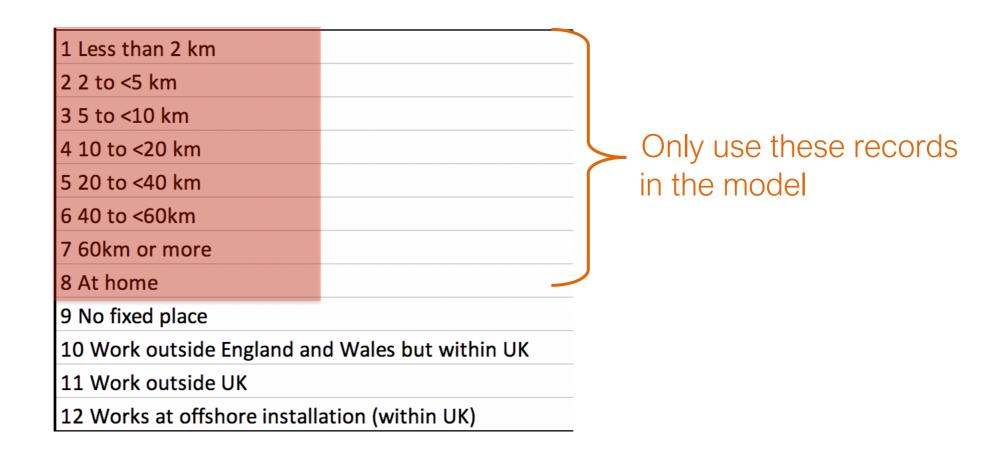

- gives the expected change in the odds for a unit change in Xs, holding all other variables constant.
- $Exp(\beta) = 1$ if $\beta = 0$: indicates is **equally likely** to occur.
- $\text{Exp}(\beta) > 1$ if $\beta > 0$: indicates an event is **more likely** to occur, or the odds are "exp(bk) times larger"
- Exp(β) < 1 if β < 0: indicates an event is less likely to occur, or the odds are "exp(bk) times smaller"

Who is Willing to Commute Long Distances?

Dependent Variable (1)

- Defining long-distance commuting using SAR:
 - Distance travelled to work categorical variable 12 cat.
 - Select cases reporting kms travelled

Dependent Variable (2)

Defining long-distance commuting using SAR:

id	distance travelled to work	long-distance commuting
1	5 to <10km	0
2	20 to <40km	0
3	60km or more	1
4	At home	0
5	60km or more	1

Travel over 60km defines as long-distance commuting

Explanatory Variables

- Gender:
 - Male (0) & Female (1)

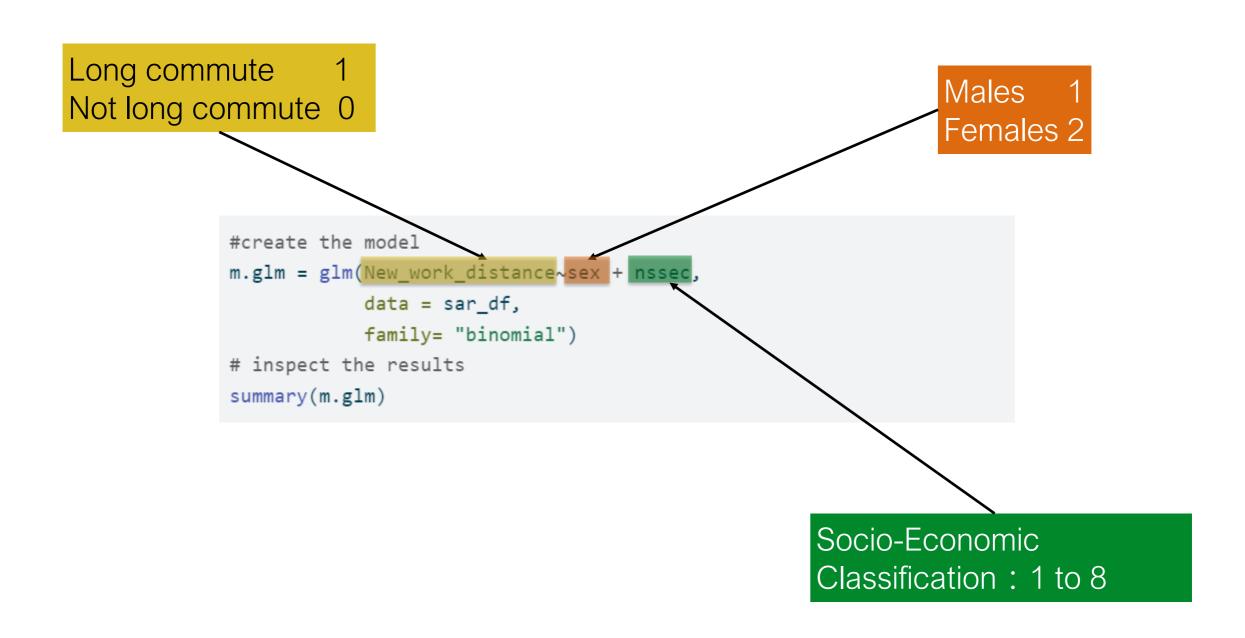

- Socio-Economic Classification:
 - 12 Categories, exclude
 - unemployed,
 - full-time students &
 - not classifiable,
 - child under 15

- 1 Large employers and higher managers
- 2 Higher professional occupations
- 3 Lower managerial and professional occupations
- 4 Intermediate occupations
- 5 Small employers and own account workers
- 6 Lower supervisory and technical occupations
- 7 Semi-routine occupations
- 8 Routine occupations
- 9 Never worked or long-term employed
- 10 Full-time student
- 11 Not classifiable
- 12 Child aged 0-15

Estimation

Estimation by using R

Y=willing to commute long distance
